Abstract

Risk factors for infection include improper care for patients, and incorrect use of infection control strategies, for that there is a need to increase the level of awareness toward infection control strategies, and to improve the practice techniques in using such strategies. In addition there is a great concern on improving the awareness of nursing students as they are trained in hospitals and they are in direct contact with patients. The purpose of this study is to assess the level of knowledge, attitude, and practice of nursing students' toward using infection control strategies in hospitals. Descriptive design was used to conduct this study, 95 nurses' students were randomly selected and included from different academic year at AAUP. The results of the study revealed that there were no significance relationship between nursing students knowledge towards infection control strategies used in hospital according to gender, academic year, and wards that have been trained in. Also there were no significance relationship between their awareness and attitude according to gender, educational level, and while in wards being trained in the result showed a significant relationship. In addition to a significance relationship between students awareness and practice according to gender, and there is no significance relationship between awareness and practice according to level of education and wards being trained in. In conclusion there must be more focus on infection control in the university lectures. In addition to initiate workshops to enhance knowledge, attitude and practice towards infection control among nursing students.

Keywords: Knowledge; Attitude; Practice; Nurses' students.

Abbreviations: AAUP: Arab American University of Palestine; P: Probability; HH: Hand Washing; HAI: Healthcare Associated Infections; SPSS: Statistical Package for Social Sciences.

Introduction

Health-care associated infections are a major safety concern worldwide for both patients and health-care providers [1]. Infection-related diseases are the main cause of death in the world, according to World Health Organization statistics [2]. The increase in infectionrelated diseases impacts the increase health financing [3]. Nurses are on the front lines who can explain infection control procedures to the patients [4]. Risk factors for infection-related diseases include lack of proper health care facilities such as isolation units, sinks, bed space; appropriate waste management, decontamination of equipment and hand hygiene facilities [5]. Education about hand hygiene is a primary prevented healthy and

Citation: Anabtawi RN, et al. Awareness of Nursing Students at AAUP towards Using Infection Control Strategies in Hospitals. Adv Nursing Patient Care Int J 2019, 2(1): 180014. safe method against infectious diseases [3]. Safe handling of sharps by using sharps box is also considered as are primary prevention [6] in addition to safe injection practice is a primary intervention for prevention of infection [2]. Using the personal protective equipment and perform appropriate ventilation are good examples of secondary infection prevention as reported by the Institute for Work and Health [7], another example of secondary infection prevention Practice is hand hygiene, and maintenance of an indwelling catheter [8].

All nurses, in all their roles can prevent and control infection by using their knowledge, experience and apply decisions towards starting appropriate interventions [9]. The majority of nurses have good knowledge and practice about nosocomial infections control in hospitals [10]. Knowledge and awareness of infection control practices among nurses were good in a tertiary care hospital in Ludhiana, India [11]. A measure was used to assess the compliance of baccalaureate nursing students in a Saudi university in using the standard precautions; it was revealed that there was a high compliance rate in disposing of used acute tools and other acute objects into specified boxes, whereas using water for hand washing had the lowest rates of compliance [12]. Adequate level of knowledge associated infections among nursing students, regarding to the suitable hand Hygiene (HH) the knowledge was hardly adequate by the third year students, and the level of knowledge about healthcare associated infections (HAI) was not enough [13]. Knowledge, attitude, and awareness of infection prevention and control among medical students were not enough as showed in the results of a study [14]. Awareness about infection prevention practices was not enough among medical students and there was a better understood of needle-stick injuries and the use of standard precautions [15]. A study conducted in a tertiary care medical college and hospital in North India that found a positive impact of educational program in improving knowledge and skills towards prevention and control of hospital associated infections [16].

The main purpose of the study is to assess the level of knowledge, attitude, and practice of nursing students' toward using infection control strategies in hospitals. In addition to increase the awareness of nursing students for the importance of using infection controls strategies in reducing spreading of infection in hospitals. The significant of this study came from the lack of prior local studies that discussed or assessed the level of nurses' student's knowledge, attitude, and practices towards using infection control protocols in hospitals.

Materials and Methods

Research design

Cross sectional descriptive design used, and a questionnaire was build up based on previous studies. The studied sample was selected randomly from 95 nursing students at Arab American University in Palestine who are in their second, third, and fourth academic year. This research was conducted in two phases. The first phase involved research reviewing relevant literatures, research, journals, publications, official reports and related information. The second phase was the primary research and involved collection of primary data via survey research with structured questionnaires. The instrument of the study consisted of two parts; Part one consisted of demographic data of the studied research sample, part two: consisted of three tables that assessing the knowledge, attitude, and practice of nursing students at AAUP towards using infection control strategies in hospital. The data was analyzed by using Statistical Package for Social Sciences (SPSS), and the results were tabulated and discussed.

Ethical considerations

For ethical considerations a permission to conduct the study in the hospitals were obtained from the authorized personnel, and consent form were signed from the nursing students who were included in the studied sample. Every participant in the study received an explanation about the purpose confidentiality of the study, participation in the study was voluntary and all data and information's gathered was strictly confidential, moreover, the participant had the right to withdrew at any time if he or she can't complete the questionnaire.

Results and Discussion

Statistical analysis

The total number of participants in the study is 95 nursing students from different academic level at Arab American University in Palestine, all of them complete the questionnaire. The included sample consisted 54.7% (n-52), while 45.3% (n=43) of them were female. 50.5% (n=48) of nursing students were in fourth academic year, 35.8% (n=34) were in third year, and 13.7% (n=13) of them were in their 2nd academic year. The results also revealed 26.3% (n=25) were trained in all wards in hospital, 20.2% (n=19) in paediatrics wards, 12.6% (n=12) in surgical wards, 11.6% (n=11) in medical wards, 10.5% (n=10) in emergency wards, 6.3% (n=6) in gynaecology wards, 6.3% (n=6) in different wards, and 6.3% (n=6) trained in more than two wards, as seen in Table 1.

T-Test results

The t-test results showed in Table 3 that there is no significance relationship between nursing students knowledge towards infection control strategies used in hospital according to gender 0.383, according to level of education 0.735, and according to wards trained in 0.838. Being male and taking training associated significantly with knowledge of prevention the infection [17]. The

same study showed that being female and being of diploma level were factors which were significantly associated with good practice of infection, this result was not consistence with the results of this study. It was found that well educated nurses were scored high levels of awareness of infection more than nurses with low awareness [18].

T-Test for Assessing Knowledge						
		Levene's Test for Equality of Variances		t-test for Equality of Means		
		F	Sig.	t	df	
Gender	Equal variances assumed	.768	.383	.536	88	
	Equal variances not assumed			.537	69.856	
Educational Level	Equal variances assumed	.115	.735	1.540	88	
	Equal variances not assumed			1.531	68.431	
Wards trained in	Equal variances assumed	.042	.838	.102	88	
	Equal variances not assumed			.103	70.909	

Table 3: Description of t-test results that shows the significance between nursing students' knowledge towards infection control strategies used in hospital according to gender, educational level and wards trained in.

As showed in Table 4, there were no significance relationship between awareness of nursing students towards infection strategies in hospital and attitude according to gender, educational level, as the result of Ttest were 0.420, 0.832 retrospective, while in wards being

trained in the result showed a significant relationship with p=0.000. This result is not consistent with study which concluded that nurses with high levels of awareness of infection were well educated [18].

		Variances		Means	
		F	Sig.	t	df
Gender	Equal variances assumed	.656	.420	1.249	87
	Equal variances not assumed			1.244	71.753
Educational Level	Equal variances assumed	.045	.832	885-	87
	Equal variances not assumed			876-	70.304
Wards trained in	Equal variances assumed	13.129	.000	1.775	87
	Equal variances not assumed			1.626	52.714

_ _ _ _

Table 4: Description of t-test results that shows the significance between nursing students' attitudes towards infection control strategies used in hospital according to gender, educational level and wards trained in.

The t-test results revealed a significance relationship between nursing students practices towards infection strategies used in hospital according gender 0.011 as showed Table 5, and there is no significant 0.046 in level of education also according to wards trained in 0.515. The result is not consistent with a previous study that concluded the education is an effective factor in practice

of infection control [18]. Regarding nursing students practice and its relation to the wards being trained in, the results is not stand by previous studies that showed a significant relationship with the unit of training [1,5], a result of a study revealed a significant relationship between nursing students practice and wards being trained in [19].

I-Test for Assessing Practice					
		Levene's Test fo	t-test for Equality of Means		
		Variances

T Test for Accessing Practice

Table 5: Description of t-test results that shows the significance between nursing students' practice towards infection control strategies used in hospital according to gender, educational level and wards trained in.

Conclusion

In conclusion the study showed that there were no significance relationship between awareness of nursing students towards infection strategies used in hospital according to gender, educational level, and wards being trained in. In addition to no significance relationship between awareness of nursing students towards infection strategies used in hospital and attitude according to gender, educational level, and while in wards being trained in the result showed a significant relationship.

In conclusion the study showed that there were no significance relationship between awareness of nursing students towards infection strategies used in hospital according to gender, educational level, and wards being trained in. In addition to no significance relationship between awareness of nursing students towards infection strategies used in hospital and attitude according to gender, educational level, and while in wards being trained in the result showed a significant relationship. The study results revealed that there is a significance relationship between practice of nursing students towards infection strategies in hospital according to gender, no significance relationship between practice of nursing students towards infection strategies in hospital according to level of education and wards trained in. According to the results there must be more focus on infection control in the university lectures, and develop training workshops for nursing students to enhance knowledge, attitude and practice towards infection control. Increase the efforts towards knowledge updating for nursing students regarding infection prevention activities.

Acknowledgements

Great acknowledgment for the students who assessed in collecting the data from the nursing students at AAUP: Esraa Ahmed Msarwa, Yara Adel Eleme, Bayan Mohamad Abu Elhija, Shaden Ibraheem Agha, Samah Amen Nujedat, Sahar Taufiq Husein.
